

4057. Number of Intersecting Interval Pairs II

Solved ●

Medium   Hint

You are given a 2D integer array `intervals` of `n` elements, where `intervals[i] = [starti, endi]` represents the **closed** interval from `starti` to `endi`.

Return the number of pairs of indices `(i, j)` such that `0 <= i < j < n` and `intervals[i]` and `intervals[j]` **intersect**.

Two intervals **intersect** if they have at least one point in common, including when they only share an endpoint.

Example 1:

Input: `intervals = [[1,2],[2,3],[3,4]]`

Output: `2`

Explanation:

There are 2 intersecting interval pairs:

- Intervals `[1, 2]` and `[2, 3]` intersect at the point 2.
- Intervals `[2, 3]` and `[3, 4]` intersect at the point 3.

Example 2:

Input: `intervals = [[1,5],[2,4],[3,6]]`

Output: `3`

Explanation:

There are 3 intersecting interval pairs:

- The intersection of `[1, 5]` and `[2, 4]` is `[2, 4]`.
- The intersection of `[1, 5]` and `[3, 6]` is `[3, 5]`.
- The intersection of `[2, 4]` and `[3, 6]` is `[3, 4]`.

Example 3:

Input: `intervals = [[1,2],[3,4],[5,6]]`

Output: `0`

Explanation:

There are no intersecting interval pairs. Hence, the answer is 0.

Constraints:

- `2 <= n == intervals.length <= 105`
- `intervals[i] = [starti, endi]`
- `0 <= starti <= endi <= 109`
